DISCLAIMER

This report has been prepared by Environmental Science staff of Greater Wellington Regional Council (GWRC) and as such does not constitute Council policy.

In preparing this report, the authors have used the best currently available data and have exercised all reasonable skill and care in presenting and interpreting these data. Nevertheless, GWRC does not accept any liability, whether direct, indirect, or consequential, arising out of the provision of the data and associated information within this report. Furthermore, as GWRC endeavours to continuously improve data quality, amendments to data included in, or used in the preparation of, this report may occur without notice at any time.

GWRC requests that if excerpts or inferences are drawn from this report for further use, due care should be taken to ensure the appropriate context is preserved and is accurately reflected and referenced in subsequent written or verbal communications. Any use of the data and information enclosed in this report, for example, by inclusion in a subsequent report or media release, should be accompanied by an acknowledgement of the source.

1. Introduction

This report summarises the key results from the Rivers State of Environment (RSoE) monitoring programme for the period 1 July 2014 to 30 June 2015 inclusive. The RSoE programme incorporates monthly monitoring of water quality, periphyton cover and sediment deposition at 53 river and stream sites across the Wellington Region. Macrophyte cover is also assessed monthly at selected RSoE sites. In addition, annual assessments of invertebrate community composition, periphyton biomass and habitat quality are conducted at all 53 RSoE sites in summer/autumn.

Note that the suitability of rivers for contact recreation purposes is reported separately under Greater Wellington Regional Council's (GWRC) recreational water quality monitoring programme; for the 2014/15 results, see Keenan et al. (2015). Information on river and stream flows is reported under GWRC's hydrological monitoring programme (see Harkness 2015).

2. Overview of RSoE monitoring programme

River and stream water quality has been routinely monitored in the western part of the Wellington Region since 1987 and in the Wairarapa since 1991. The monitoring programme has continued to evolve since this time with changes made to the location and number of monitoring sites, the range of variables monitored, and the methods of analysis (see Milne and Perrie (2005) and Perrie et al. (2012) for details). However, since September 2003, the RSoE monitoring programme has remained largely unchanged, with only minor changes to the existing suite of monitoring sites and variables.

2.1 Monitoring objectives

The aims of GWRC's Rivers SoE monitoring programme are to:

1. Assist in the detection of spatial and temporal changes in rivers and streams;
2. Contribute to our understanding of freshwater biodiversity in the Wellington Region;
3. Determine the suitability of rivers and streams for designated uses;
4. Provide information to assist in targeted investigations where remediation or mitigation of poor water quality or ecosystem health is desired; and
5. Provide information required to determine the effectiveness of regional plans and policies.

2.2 Monitoring network

Water quality and ecosystem health are currently monitored at 53 river and stream sites (Figure 2.1, Appendix 1). These sites were chosen to represent the major land uses and human activities, and also the natural diversity of rivers and streams, in the Wellington Region.

2.2.1 Changes to the monitoring network

During 2014/15 monitoring ceased at two sites because regular access was considered no longer safe. These sites were Coles Creek Tributary at Lagoon Hill Road (RS54) and Mataikona Tributary at Sugar Loaf Road (RS35) which were last sampled in June 2014 and August 2014, respectively.

2.3 Monitoring variables

2.3.1 Water quality variables

River and stream water quality is assessed at monthly intervals by measuring a range of physico-chemical and microbiological variables: dissolved oxygen, temperature, pH, conductivity, visual clarity, turbidity, suspended solids, faecal indicator bacteria, total organic carbon, and dissolved and total nutrients. Water samples from ten RSoE sites located in urban catchments with likely exposure to heavy metal inputs, or which discharge into sensitive downstream receiving environments (eg, harbours and estuaries), are also analysed for dissolved concentrations of copper and zinc. The full list of variables monitored, together with details of field and analytical methods, is provided in Appendix 2.

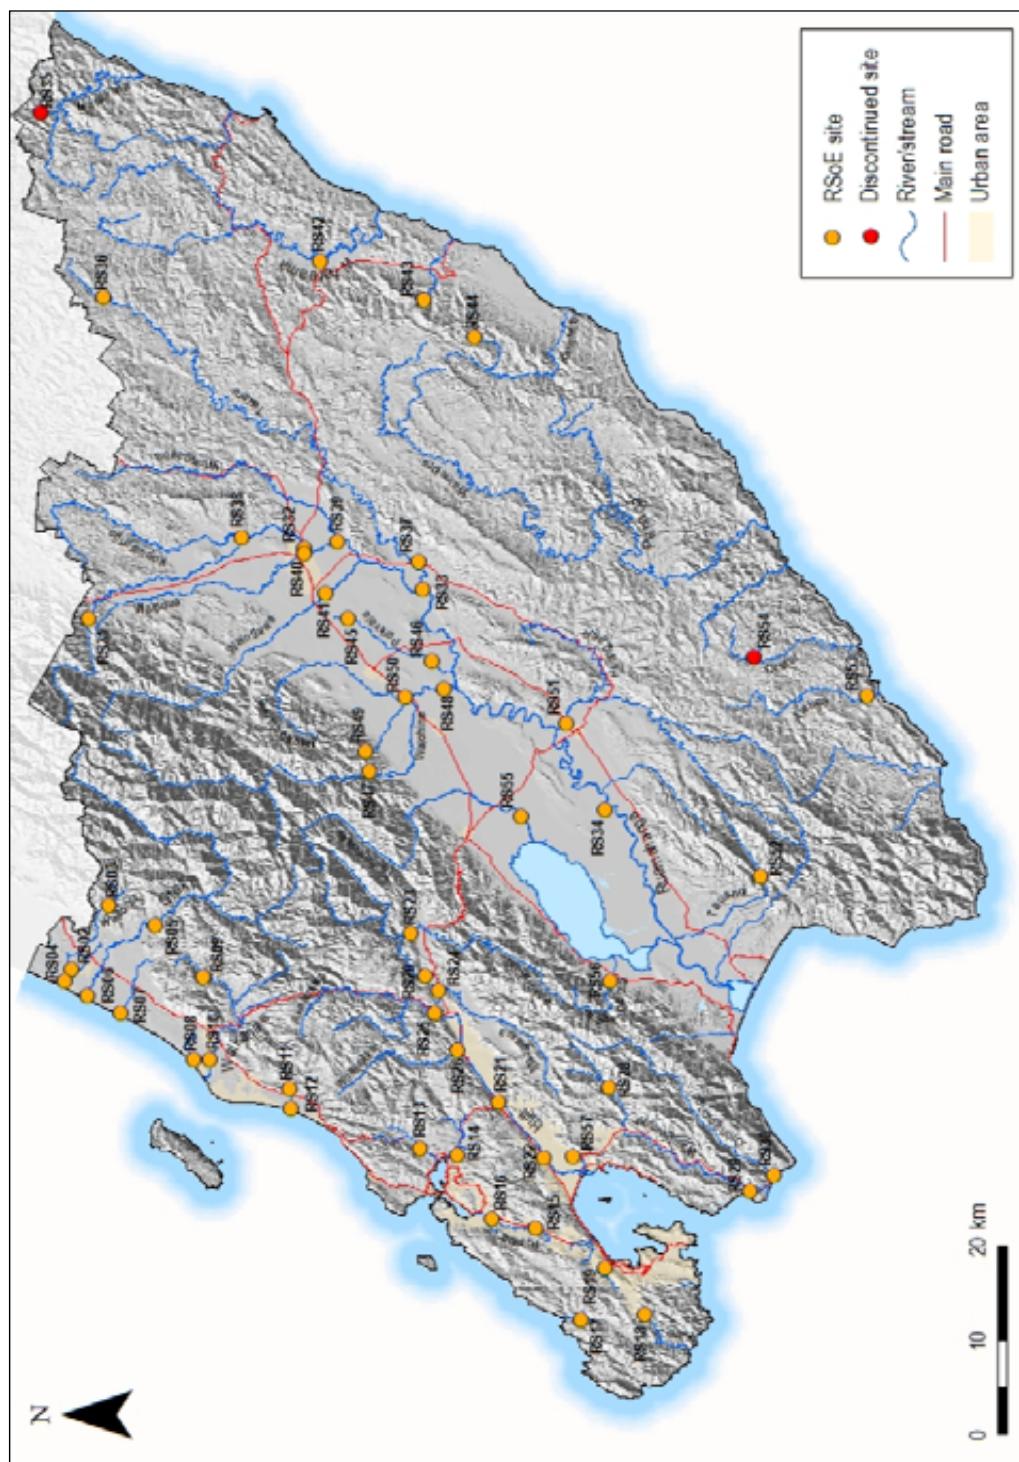

Figure 2.1: RSoE sites monitored over 2014/15

2.3.2 Biological variables

Rivers and streams are also assessed for ecological condition. This involves semi-quantitative assessments of macroinvertebrate communities and periphyton biomass during stable/low flows in summer/autumn. Assessments of periphyton are only undertaken at sites with hard substrates such as cobbles and large gravel (44 in total, see Appendix 1 for RSoE site substrate types). Periphyton cover is also assessed monthly at these sites at the time of water sample collection.

Macrophyte cover is assessed at RSoE sites that are soft-bottomed and hence more likely to support macrophyte communities. Macrophyte cover is also assessed at hard-bottomed sites known to have, at least at times, high macrophyte cover.

Details of current biological monitoring methods are summarised in Appendix 2.

2.3.3 Habitat variables

Habitat assessments are undertaken annually at each RSoE site during summer/early autumn (at the time biological samples are collected). This assessment provides an indication of the condition of the physical habitat and its ability to support stream biota, and incorporates the following variables: fine sediment cover, invertebrate habitat abundance and diversity, fish habitat abundance and diversity, hydraulic heterogeneity, bank stability, channel modification, and riparian buffer width, integrity and shade. Fine sediment cover is also assessed monthly at the time of water sample collection. Details of current habitat assessment methods are summarised in Appendix 2.

2.3.4 Changes to monitoring variables in 2014/15

In 2014/15, there were three changes to the variables monitored:

- Lower analytical detection limits for some nutrients (ammoniacal nitrogen, nitrate nitrogen, nitrite nitrogen and dissolved reactive phosphorus) were implemented from January 2015 onwards (see Table A2.1, Appendix 2) following an initial paired trial of nutrient test methods during 2013/14 (see Heath et al. 2014);
- Periphyton taxonomic identification ceased; and
- Macrophyte channel cogginess was calculated from macrophyte assessments undertaken (see Appendix 2).

2.4 Additional river monitoring during 2014/15

During 2014/15, GWRC (along with several other regional councils) participated in a NIWA-led trial that looked at fostering and supporting community-based monitoring of rivers in New Zealand. This involved community groups and GWRC both sampling water quality (monthly) and macroinvertebrates (biannually) at three sites across the region; two existing RSoE sites (Mangatarere Stream at SH2 and Waikanae River at Greenaway Road) and one new site, Mawaihakona Stream at Hutt Confluence.

A key aim of the project was to compare data collected by community groups and that collected by trained council field staff (GWRC) in order to assess how community group monitoring can be used to increase community engagement and extend the monitoring capacity of regional councils. Additional data collected by GWRC as part of this trial is presented in Appendix 7.

3. Physico-chemical and microbiological water quality

3.1 Approach to analysis

In this section a water quality index is used as a comparative measure to summarise water quality across the Wellington Region, based on physico-chemical and microbiological data collected monthly from July 2014 to June 2015 inclusive (see Appendix 3 for tabulated data). Concentrations of heavy metals (copper and zinc) recorded at selected urban sites are also summarised (Appendix 4). The summary information is typically based on 12 sampling events for all 53 sites. However, sampling at some sites was not always possible due to access issues (eg, during lambing or calving) or safety concerns (eg, high river flows).

During data processing, any water quality variables reported as less than or greater than detection limits were replaced by values one half of the detection limit or the detection limit, respectively (eg, a value of <2 became 1, a value of >400 became 400). The exception is minimum values reported in the tabulated summaries in Appendices 3 and 4 (ie, if a value was reported as <2 the minimum value presented is <2).

3.1.1 Water quality index

A water quality index (WQI), as described by Perrie (2007) and Perrie et al. (2012), is used to facilitate inter-site comparisons of the state of water quality in the region's rivers and streams. The WQI is derived from the *median* values of the following six variables: visual clarity (black disc), dissolved oxygen (% saturation), dissolved reactive phosphorus, ammoniacal nitrogen, nitrite-nitrate nitrogen and *Escherichia coli* (*E. coli*).

The application of the WQI enables water quality at each site to be classified into one of four categories, as follows:

- Excellent: median values for all 6 variables comply with guideline values
- Good: median values for 5 of the 6 variables comply with guideline values, of which dissolved oxygen is one variable that must comply¹
- Fair: median values for 3 or 4 of the 6 variables comply with guideline values, of which dissolved oxygen is one variable that must comply¹
- Poor: median values for <3 of the 6 variables comply with guideline values, or the median dissolved oxygen concentration/value does not comply with the guideline value.

The guidelines used in the WQI assessment are listed in Table 3.1. Refer to Perrie (2007) and Perrie et al. (2012) for further discussion on these guidelines.

¹ If the median dissolved oxygen concentration does not comply with the guideline value, then the WQI grade automatically drops to 'poor'.

Table 3.1: Physico-chemical and microbiological variables and guideline values used in GWRC's WQI

Variable	Guideline value	Reference
Dissolved oxygen (% saturation)	≥ 80	RMA 1991 Third Schedule
Visual clarity (m)	≥ 1.6	MfE (1994)
Nitrite-nitrate nitrogen (mg/L)	≤ 0.444	ANZECC & ARMCANZ (2000)
Ammoniacal nitrogen (mg/L)	≤ 0.021	ANZECC & ARMCANZ (2000)
Dissolved reactive phosphorus (mg/L)	≤ 0.010	ANZECC & ARMCANZ (2000)
<i>E. coli</i> (cfu/100mL)	≤ 100	ANZECC & ARMCANZ (2000)

As outlined in Perrie (2007), the WQI is for comparative purposes rather than an absolute measure of water quality; sites with a grade of ‘good’, ‘fair’, or ‘poor’ are all considered degraded to some degree because the median value of at least one of the six physico-chemical or microbiological variables in the WQI exceeded a guideline value. In addition, as the WQI is based on median values (ie, 50% compliance), sites awarded the same water quality grade may exhibit varying degrees of compliance (from 51 to 100% with the guideline value). Therefore, to differentiate between ‘better’ and ‘poorer’ sites, the sites within each WQI class are ranked based on the number of guideline exceedances for each of the six key variables (eg, a site that exceeded a guideline on 40% of sampling occasions will be ranked lower than a site with the same WQI grade that exceeded the same guideline on 10% of sampling occasions).

3.1.2 Heavy metals

Median heavy metal concentrations are compared against ANZECC (2000) chronic toxicity ‘trigger values’ (95% level of protection). Because water hardness affects the toxicity of some heavy metals, where a median concentration exceeds the trigger value, site-specific, hardness-modified trigger values are calculated based on recommendations and equations in ANZECC (2000). The median concentrations are then compared against their respective modified trigger value. Because water hardness is not part of the existing suite of variables analysed in the RSoE programme, the median water hardness from monthly monitoring over July 2012 to June 2013 (inclusive) is used as a surrogate of local water hardness conditions (see Morar & Perrie (2013) for hardness information).

3.2 Results

3.2.1 Water quality index

Application of the WQI resulted in the following overall water quality grades for the 53 RSoE sites monitored in the Wellington region over the July 2014 to June 2015 reporting period (Table 3.2; Figure 3.1):

- Excellent: 21 sites (39.6%)
- Good: 6 sites (11.3%)
- Fair: 15 sites (28.3%)
- Poor: 11 sites (20.8%)

Table 3.2: Water Quality Index grades for RSoE sites sampled at monthly intervals over July 2014 to June 2015 inclusive, based on compliance of median dissolved oxygen (DO), visual clarity (clarity), *E. coli*, nitrite-nitrate nitrogen (NNN), ammoniacal nitrogen (Amm. N) and dissolved reactive phosphorus (DRP) values with guideline values

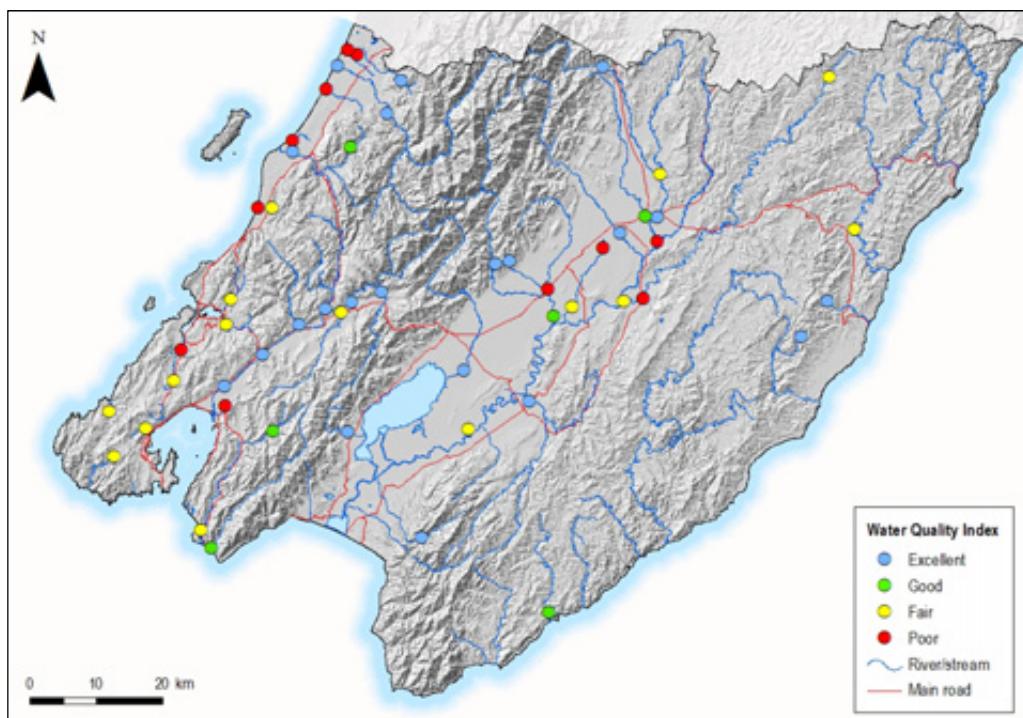

Figure 3.1: Water Quality Index grades for RSoE sites sampled at monthly intervals between July 2014 and June 2015, based on compliance of median dissolved oxygen, visual clarity, nitrite-nitrate nitrogen, ammoniacal nitrogen, dissolved reactive phosphorus and *E. coli* values with guideline values

Seventeen of the 21 RSoE sites graded ‘excellent’ are located on river and stream reaches in catchments with predominantly unmodified indigenous forest cover (refer to Appendix 1 for dominant land cover). These tend to be sites on rivers flowing out of the Aorangi, Tararua and Rimutaka ranges and include the Hutt, Otaki, Tauanui and Waiorongomai rivers, and the upper reaches of the Waitohu Stream and Ruamahanga River. In contrast, RSoE sites graded ‘poor’ are typically located on small rivers or streams draining predominantly pastoral (seven sites) or urban (four sites) catchments. Sites with the poorest water quality during 2014/15 were Mangaone Stream at Sims Road Bridge and Mangapouri Stream at Bennetts Road (Table 3.2).

The water quality variables that most commonly failed to meet guideline values (based on median values) were dissolved reactive phosphorus (25 sites), followed by *E. coli* (24 sites), clarity (16 sites) and nitrite-nitrate nitrogen (15 sites). Guidelines for ammoniacal nitrogen and dissolved oxygen were not met at six and four sites, respectively.

3.2.2 Heavy metals

Median concentrations of dissolved copper exceeded the ANZECC (2000) default trigger value at two sites (Karori Stream at Makara Mountain Bike Park and Kaiwharawhara Stream at Ngaio Gorge), although neither of these sites had median concentrations exceeding their site-specific, hardness-modified trigger value. Based on median values, three sites (Karori Stream at Makara Mountain Bike Park, Porirua Stream at Wall Park and Waiwhetu Stream at

Whites Line East) exceeded both the ANZECC (2000) default trigger value and their site-specific, hardness-modified trigger value for dissolved zinc. Summary statistics for heavy metals can be found in Appendix 4.

4. Periphyton and macrophytes

4.1 Approach to analysis

Assessment of periphyton is limited to RSoE sites with hard substrates (44 of the 53 sites). Monthly observations of percent streambed periphyton cover (filamentous and mat-forming (including cyanobacteria) periphyton) from July 2014 to June 2015 inclusive, and an assessment of periphyton biomass (chlorophyll *a* and Ash Free Dry Mass (AFDM)) undertaken in summer 2014/15 are compared against various MfE (2000) guidelines (Table 4.1). Monthly cover assessments of potentially toxic mat-forming cyanobacteria are compared against the MfE and MoH (2009) guidelines (Table 4.2). Macrophyte cover and macrophyte channel cogginess², measured monthly at 16 RSoE sites, is also summarised.

Table 4.1: MfE (2000) guidelines used to assess periphyton streambed cover and biomass

Instream value/variable	Mat periphyton	Filamentous periphyton
Aesthetics/recreation		
Maximum cover of visible streambed	60% >0.3 cm thick	30% >2 cm long
Benthic biodiversity		
Maximum chlorophyll <i>a</i>	50 mg/m ²	50 mg/m ²
Trout habitat and angling		
Maximum AFDM	35 g/m ²	35 g/m ²
Maximum cover of visible streambed	N/A	30% >2 cm long

Table 4.2: MfE/MoH (2009) alert framework for benthic cyanobacteria cover in rivers

Alert level	Guideline
Green	≤20% coverage of potentially toxic cyanobacteria attached to substrate
Amber	20–50% coverage of potentially toxic cyanobacteria attached to substrate
Red	>50% coverage of potentially toxic cyanobacteria attached to substrate

¹ The red alert level is slightly modified from the MfE and MoH (2009) guidelines; detached mats are not recorded.

4.2 Results

The number of observations of streambed periphyton cover made during the reporting period varied among the 44 RSoE sites due to either site access being restricted or because turbid water or high flows prevented periphyton assessments being carried out on some occasions. Observations for some sites in the Ruamahanga River catchment were particularly few in number as a result of sampling often coinciding with high river flows during or following rainfall.

² Essentially how "clogged" up a stream channel is with macrophytes.

Of the 44 RSoE sites with periphyton observations, 13 exceeded the MfE (2000) guideline for filamentous periphyton streambed cover on at least one sampling occasion (Table 4.3). The sites that most often exceeded the guideline were Huangarua River at Ponatahi Bridge, Awhea River at Tora Road and Pauatahanui Stream at Elmwood Bridge. These sites are all located in catchments dominated by pastoral land use.

No sites exceeded the MfE (2000) guideline for mat-forming periphyton cover during the reporting period. However, one site (Waipoua River at Colombo Road Bridge) on one occasion exceeded the MfE/MoH (2009) alert ‘Amber’ guideline for benthic mat-forming cyanobacteria cover.

Twelve RSoE sites exceeded the MfE (2000) chlorophyll *a* guideline for benthic biodiversity (Table 4.4). The highest chlorophyll *a* biomass recorded was in the Huangarua River at Ponatahi Bridge (342.3 mg/m^2). The Huangarua River at Ponatahi Bridge was also the only site that exceeded the MfE (2000) AFDM guideline for trout habitat and angling, with a result of 42.8 g/m^2 .

Overall, 28 of the 44 monitored sites complied with all of the periphyton guidelines. There was a reasonable relationship between periphyton guideline compliance and WQI grades. In general, sites with ‘excellent’ water quality were more likely to comply with guidelines for periphyton cover and biomass than sites assigned lower WQI grades. However, at some sites variables other than water quality, such as accrual periods and streamside shade, more strongly influence periphyton growth and hence compliance with guidelines.

A summary of total streambed macrophyte cover and macrophyte channel cogginess data is presented in Table 4.5. Sites that recorded the highest median cover were Parkvale tributary at Lowes Reserve (80%), Waiwhetu Stream at Whites Line East (72%) and Mangaone Stream at Sims Road Bridge (60%). Parkvale tributary at Lowes Reserve and Mangaone Stream at Sims Road Bridge also had the highest median macrophyte channel cogginess (80% and 60%, respectively).

Table 4.3: Summary of monthly observations at RSoE sites, over July 2014 to June 2015 inclusive, of visible streambed periphyton cover in relation to exceedances of the MfE (2000) and MfE & MoH (2009) guidelines

Site no.	Site name	<i>n</i>	Streambed cover						
			Filamentous (>2 cm long)		Mats ¹ (>0.3 cm thick)		Cyanobacterial mats ¹ (>0.1 cm thick)

5. Macroinvertebrates

5.1 Approach to analysis

Macroinvertebrate sampling was undertaken at each of the 53 RSoE sites during summer 2014/15. The Macroinvertebrate Community Index (MCI), an index of sensitivity to a wide range of environmental variables (Stark & Maxted 2007), is used to summarise macroinvertebrate health. Additional macroinvertebrate indices (QMCI, %EPT taxa, and taxa richness)³ are presented in Appendix 5. Refer to Perrie et al. (2012) for further explanation of these indices.

The quality classifications, as recommended by Stark and Maxted (2007), for interpretation of the MCI scores are outlined in Table 5.1. Soft bottomed MCI scores (MCI-sb) have also been calculated for the nine RSoE sites with soft substrates (see Appendix 1).

Table 5.1: Interpretation of MCI-type scores (from Stark & Maxted 2007)

Quality class	MCI and MCI-sb
Excellent	≥ 120
Good	100–119
Fair	80–99
Poor	<80

5.2 Results

The MCI scores based on one sample collected from each monitoring site are presented in Table 5.2. The 53 RSoE sites fell into the following MCI quality classes (Figure 5.1):

- Excellent: 15 sites (28.3%)
- Good: 17 sites (32.1%)
- Fair: 13 sites (24.5%)
- Poor: 8 sites (15.1%)

All of the RSoE sites in the ‘excellent’ MCI quality class are located in catchments dominated by indigenous forest cover (eg, sites located in the upper reaches of the Otaki, Waikanae, Hutt and Ruamahanga rivers). Seven of the eight RSoE sites in the ‘poor’ quality class have soft-sediment substrate and all eight sites are located in catchments dominated by either pastoral landcover (five sites) or urban landcover (three sites).

There was a reasonable relationship between the MCI quality classes and WQI grades. For example, of the 15 RSoE sites with an ‘excellent’ MCI quality class, 13 had a WQI grade of ‘excellent’ and two a WQI grade of ‘good’. Similarly, of the eight RSoE sites with an MCI quality class of ‘poor’, six had a WQI grade of ‘poor’ and two had a WQI grade of ‘fair’. The relationship between water quality and macroinvertebrate health based on WQI grades and MCI quality grades was less clear in the ‘good’ and ‘fair’ classes.

³ QMCI = Quantitative MCI and %EPT taxa = the percentage of pollution-sensitive Ephemeroptera (mayfly), Plecoptera (stonefly) and Trichoptera (caddisfly) taxa. See Perrie et al. (2012) for index calculation details.

Table 5.2: MCI scores for RSoE sites sampled in summer 2014/15

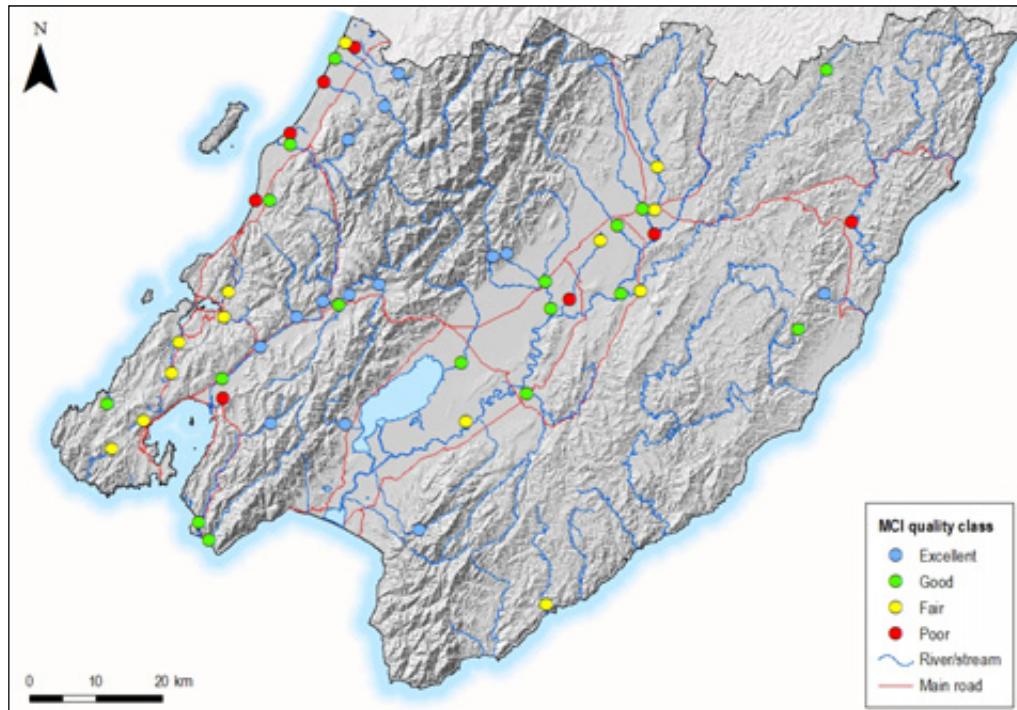

Figure 5.1: MCI quality classes for the 53 RSoE sites, determined from one sampling event over summer 2014/15

Sites that recorded higher MCI scores were also more likely to comply with both periphyton cover and biomass guidelines. Of the 28 sites that complied with all periphyton guidelines, 14 had MCI grades of 'excellent' and eight sites had MCI scores of 'good'.

6. Habitat quality

6.1 Approach to analysis

Habitat assessments were undertaken at each of the 53 RSoE sites at the time annual biological samples were collected in summer 2014/15. A summary of the overall habitat scores for each site is provided (individual scores for each of the nine components that make up the overall habitat score can be found in Appendix 6); these overall scores provide an indication of the physical stream habitat condition and its ability to support stream biota.

Streambed fine sediment cover was assessed monthly at the time of water sample collection. A tabulated summary of these monthly assessments is presented.

6.2 Results

6.2.1 Habitat assessment

Overall habitat scores ranged from 60 (Mangaone Stream at Sims Road Bridge) to 217.5 (Waikanae River at Mangaone Walkway) with a median score across all 53 sites of 147.5 (Table 6.1). The 14 RSoE sites that had the highest habitat scores were all located in catchments with indigenous forest as the dominant landcover and had hard-bottomed substrate (eg, Waikanae River at Mangaone Walkway and Wainuiomata River at Manuka Track). These sites also had ‘excellent’ MCI classification and ‘excellent’ or ‘good’ WQI classifications. In contrast, the RSoE sites that had the lowest habitat scores were all located in catchments dominated by either pastoral or urban landcover and tended to have soft-sediment substrates (eg, Waitohu Stream at Norfolk Crescent and Waiwhetu Stream at Whites Line East). The sites with the lowest habitat scores were more likely to record ‘fair’ or ‘poor’ MCI and WQI classes.

6.2.2 Fine sediment cover

The number of observations of fine sediment streambed cover made during the reporting period varied among the 53 sites due to site access being restricted, or turbid water or high flows inhibiting the assessment⁴. Unsurprisingly, most (six) of the nine sites considered ‘soft-bottomed’ typically had high proportions of fine sediment cover (ie, median values >50% cover) (Table 6.1). Of the 44 RSoE sites considered hard-bottomed, median fine sediment cover values ranged from 0 (at 13 sites, eg, Ruamahanga River at McLays) to >50% at three sites (Makara Stream at Kennels, Awheia River at Tora Road and Pauatahanui Stream at Elmwood Bridge). Sites that had higher median values for fine sediment streambed cover tended to be located on smaller streams, mostly on the Kapiti Coast (eg, Mangapouri Stream at Bennetts Road) or in eastern Wairarapa (eg, Tauheru River at Castlehill).

While sites that had low median fine sediment cover scores tended to be located in indigenous forest catchments, obvious relationships between dominant landuse and fine sediment cover were not overly apparent, indicating that factors such as catchment geology and hydrology (flushing flows) are also important.

⁴ Over the reporting period, turbid and/or humic stained water limited the number of monthly fine sediment assessments carried out at the Ngarara Stream at Field Way and Whareroa Stream at QE Park to zero and one, respectively (Table 6.1).

Table 6.1: Overall habitat quality scores based on a one-off assessment and summary of monthly observations of fine sediment (<2 mm) streambed cover at RSoE sites during 2014/15

*RSoE sites where water samples are also analysed for selected heavy metals.

**REC landcover class changed to reflect more up-to-date catchment scale landcover information from MfE (2010).

Appendix 2: Monitoring variables and methods

Physico-chemical and microbiological water quality

Core water quality variables measured/analysed at each RSoE site are presented in Table A2.1. As far as practicable, individual RSoE monitoring sites are sampled at the same time of the month (and usually at the same time of the day) throughout the year, and where possible all sites on a river or stream are sampled on the same day. Field meters are calibrated on the morning of the day of sampling. Water samples are collected in mid-stream (where possible), typically in run-type habitat from a representative reach of stream. Samples requiring laboratory analysis are placed in chillibins with ice and couriered overnight to RJ Hill Laboratories in Hamilton. Water samples for heavy metal and dissolved nutrient analysis were all laboratory filtered.

Table A2.1: RSoE field and analytical water quality methods and detection limits

Variable	Method	Detection limit
Water temperature	Field meter – generally YSI ProODO	0.01 °C
Dissolved oxygen	Field meter – generally YSI ProODO	0.01 mg/L
Visual clarity	Black disc (20 mm disc if clarity <0.5 m, 60 mm disc for clarity between 0.5 m and 1.5 m, 200 mm disc for clarity >1.5 m)	0.01 m
pH	Field meter – generally YSI Professional Plus	0.01 units
Conductivity	Field meter – generally YSI Professional Plus	0.1 µS/cm
Turbidity	Analysis using a Hach 2100N, Turbidity meter. APHA 2130 B 22nd Ed. 2012	0.05 NTU
Total suspended solids	Filtration using Whatman 934 AH, Advantec GC-50 or 1-2 equivalent filters (nominal pore size 1.2–1.5µm), gravimetric determination. APHA 2540 D 22nd Ed. 2012	2 mg/L
Total organic carbon	Catalytic oxidation, IR detection, for Total C. Acidification, purging for Total Inorganic C. TOC = TC–TIC. APHA5310 B 22nd Ed. 2012	0.5 mg/L
Ammoniacal nitrogen	Filtered sample. Phenol/hyperchlorite colorimetry. Discrete Analyser. ($\text{NH}_4\text{-N} = \text{NH}_4^+ + \text{NH}_3\text{-N}$) APHA 4500-NH ₃ F (modified from manual analysis) 22nd Ed. 2012	0.01 mg/L until Dec. 2014 0.005 mg/L from Jan. 2015
Nitrite nitrogen	Automated Azo dye colorimetry, Flow injection analyser. APHA 4500-NO ₂ -I (Modified) 22nd Ed. 2012	0.002 mg/L until Dec. 2014 0.001 mg/L from Jan. 2015
Nitrate nitrogen	Calculation: (Nitrate-N + Nitrite-N) – Nitrite-N	0.002 mg/L until Dec. 2014 0.001 mg/L from Jan. 2015
Nitrate + nitrite nitrogen	Total oxidised nitrogen. Automated cadmium reduction, Flow injection analyser. APHA 4500-NO ₃ -I (Modified) 22nd Ed. 2012	0.002 mg/L until Dec. 2014 0.001 mg/L from Jan. 2015
Total Kjeldahl nitrogen	Kjeldahl digestion, phenol/hyperchlorite colorimetry (Discrete Analysis). APHA 4500-N Org C. (modified) 4500-NH ₃ F (modified) 22nd Ed. 2012	0.1 mg/L
Total nitrogen	Calculation: TKN + Nitrate-N + Nitrite-N	0.11 mg/L ¹
Total phosphorus	Total Phosphorus digestion, ascorbic acid colorimetry. Discrete Analyser. APHA 4500-P E (modified from manual analysis) 22nd Ed. 2012	0.004 mg/L
Dissolved reactive phosphorus	Filtered sample. Molybdenum blue colorimetry. Discrete Analyser. APHA 4500-P E (modified from manual analysis) 22nd Ed. 2012	0.004 mg/L until Dec. 2014 0.001 mg/L from Jan. 2015
Faecal coliforms	APHA 9222D 22 nd Ed. 2012	1 cfu/100mL
<i>E. coli</i>	APHA 9222G 22 nd Ed. 2012	1 cfu/100mL
Dissolved copper	Filtered sample, ICP-MS, trace level. APHA 3125 B 22nd Ed. 2012	0.0005 mg/L
Dissolved zinc	Filtered sample, ICP-MS, trace level. APHA 3125 B 22nd Ed. 2012	0.0010 mg/L

¹ A detection limit of 0.05 mg/L can be achieved if samples are analysed in duplicate.

Periphyton

Formal periphyton assessments are limited to the 44 RSoE sites with hard substrates.

Monthly assessment of visible streambed cover

Periphyton cover is determined by estimating the percentage of mat (>0.3 cm thick), cyanobacterial mat (>0.1 cm thick) and filamentous (>2 cm long) periphyton present on the stream or river bed. Note that cover of mat and cyanobacterial mat-periphyton are not mutually exclusive (ie, cyanobacterial mat cover >0.3 cm thick will also be counted as mat-periphyton). A total of 20 observations are undertaken at each site from two transects of ten observations or, if the stream or river is not wide enough or too deep/swift to wade across more than half of the river's width, four transects of five observations. Each observation is typically made with an underwater viewer and covers an approximate area of a 30 cm diameter circle.

Visible streambed periphyton cover assessments are carried out equally in both run and riffle-type habitats if these are present at a sampling site/reach.

Annual assessment of biomass and relative abundance

Periphyton samples for quantitative biomass assessments (chlorophyll *a* and Ash Free Dry Matter) are collected during late summer/early autumn at the time of macroinvertebrate sample collection. Sampling protocols follow a modified version of quantitative method 1a (QM-1a), as outlined by Biggs and Kilroy (2000) that involves pooling periphyton samples from 10 rocks into a single composite sample for analysis.

Biomass assessments are carried out on periphyton samples collected in riffle-type habitats in close proximity to macroinvertebrate sampling sites.

Macrophytes

Macrophyte cover is assessed monthly at 16 of the 53 RSoE sites (at the time of water sample collection). These sites were selected because they are either soft-bottomed sites and hence are more likely to support macrophyte communities and/or were known to have, at least at times, moderate to high macrophyte cover.

Macrophyte cover is assessed following the method in Collier et al. (2007) except that information on the native and exotic components of the macrophyte community are not recorded. This method provides a general overview of reach scale rooted macrophyte cover (Collier et al. 2007) and involves estimating the proportion of emergent, surface reaching and submerged rooted macrophyte cover in 1 m strips at 5 evenly spaced transects along a sampling reach (~50–100 m). The proportion of channel cross sectional area (or volume) occupied by the submerged macrophyte cover in each transect is also estimated to feed into the channel cogginess calculation (following Matheson et al. 2012). Macrophyte indices are calculated as follows:

- Total macrophyte cover = $\sum (\% \text{ emergent cover} + \% \text{ surface reaching cover} + \% \text{ submerged cover})/5$
- Macrophyte channel cogginess = $\sum (\% \text{ emergent cover} + \% \text{ surface reaching cover} + (\% \text{ submerged cover} * \% \text{ channel cross sectional area occupied by submerged cover}))/5$

Note: Collier et al. (2007) state that this method is most suitable for wadeable streams. Undertaking this assessment in non-wadeable streams, as well streams that are turbid or experiencing elevated flows, may result in less reliable estimates of reach scale macrophyte cover.

Macroinvertebrates

A single macroinvertebrate sample is collected at or adjacent to each RSoE water sampling site during summer/early autumn. The timing of sampling is determined at random, although macroinvertebrate sampling is, where practicable, avoided within two weeks of any flood event (flood events are defined as flows greater than three times the median river flow).

Samples are collected with the use of a kick-net (0.5 mm mesh size) following Protocol C1 of the national macroinvertebrate sampling protocols (Stark et al. 2001) for the 44 RSoE sites with hard substrate (in riffle habitat) and Protocol C2 for the nine RSoE sites with a soft substrate. All samples are processed in accordance with Protocol P2 (Stark et al. 2001).

Habitat quality assessments

Habitat assessments are undertaken annually at each of the 53 RSoE sites during summer/early autumn (at the time biological samples are collected) following the methods outlined in Clapcott (2013). This assessment provides an indication of the condition of the physical habitat and its ability to support stream biota, and incorporates the following variables: fine sediment cover, invertebrate habitat abundance and diversity, fish habitat abundance and diversity, hydraulic heterogeneity, bank stability, channel modification and riparian buffer width, integrity and shade. Each category is scored between 1 ('poor') and 20 ('excellent') with both invertebrate and habitat categories weighted double that of the other variables. Summation of individual scores provides an overall total habitat quality score for each site (lowest and highest possible scores are 11 and 220, respectively).

Note that the habitat assessment methodology is considered a working draft and is expected to be refined over time. This methodology was also developed with a focus on wadeable hard-bottomed streams (Clapcott 2013) and hence its applicability to other stream/river types has not been explored.

Fine sediment streambed cover

Assessments of fine sediment streambed cover are undertaken monthly and coincide with the collection of water samples at each of the 53 RSoE sites using a modified version of Sediment Assessment Method 1 (Clapcott et al. 2011; bankside visual estimate of % sediment cover). This method involves a relatively quick visual estimate of the proportion fine sediment (<2 mm) cover of the streambed and it is undertaken from the bankside of the river. Visual estimates are typically made in run-type habitat over a representative reach (typically 20–50 m) and information on the length and width of streambed assessed is also recorded. The modification to the method is that, apart from sand, proportions of streambed cover of other substrates (eg, gravels, cobbles, etc.) are not estimated.

*Lower n counts for some sites (when compared to other variables) reflects sampling occasions when the field pH meter had malfunctioned and no measurement could be made. In such instances, the lab was asked to measure pH from a supplied water sample.

*Lower *n* counts for some sites (when compared to other variables) reflects sampling occasions when the field conductivity meter had malfunctioned and no measurement could be made. In such instances, the lab was asked to measure conductivity from a supplied water sample.

Appendix 7: Additional monitoring data for 2014/15

Table A7.1 summarises water quality, periphyton and fine sediment data collected as part of the community-based river monitoring trial (refer Section 2.4). Macroinvertebrate metrics presented for existing RSoE sites in Table A7.2 are based on samples collected on different occasions to those summarised in Section 5.

Water quality and macroinvertebrate samples were typically collected in accordance with methodology outlined in Appendix 2, except that in some cases macroinvertebrate samples were collected during winter/spring periods.

Table A7.1:Summary of water quality, periphyton and fine sediment data collected in the Mawaihakona Stream at Hutt Confluence, based on 12 sampling occasions between July 2014 and June 2015¹

Variable	Median	Minimum	Maximum	n
Water temperature (°C)	15.7	11.9	19.9	12
Dissolved oxygen (% saturation)	115.9	91.9	138.9	12
Dissolved oxygen (mg/L)	11.5	9.5	12.9	12
pH	7.2	6.7	8.2	11
Water clarity (m)	2.12	0.66	4.54	12
Turbidity (NTU)	1.4	0.3	5.4	12
Total suspended solids (mg/L)	3.5	<2.0	11	12
Conductivity (µS/cm)	133.2	89.9	145.8	12
Total organic carbon (mg/L)	1.7	0.9	3.9	12
Ammoniacal nitrogen (mg/L)	0.005	<0.010	0.031	12
Nitrite-nitrate nitrogen (mg/L)	1.150	0.510	1.590	12
Total Kjeldahl nitrogen (mg/L)	0.150	0.110	0.240	12
Total nitrogen (mg/L)	1.300	0.680	1.770	12
Dissolved reactive phosphorus (mg/L)	0.013	0.006	0.020	12
Total phosphorus (mg/L)	0.021	0.015	0.039	12
<i>E. coli</i> (cfu/100 mL)	145	40	2,400	12
Faecal coliforms (cfu/100 mL)	165	50	2,900	12
Fine sediment (% cover)	50	30	70	11
Filamentous periphyton (% cover)	1	0	4	11
Mat periphyton (% cover)	0	0	9	11
Cyanobacteria mat periphyton (% cover)	1	0	3	11

¹Note that additional water quality data are available for this site (sampling has occurred monthly from March 2014 to August 2015 inclusive).

Table A7.2: Summary of macroinvertebrate metrics based on additional samples/sites collected between July 2014 and June 2015¹ as part of the community based river monitoring trial

Site	Sampling date	MCI	QMCI	%EPT taxa	TAXA richness
Mawaihakona S at Hutt confluence	19/08/2014	75.0	3.24	12.5	16
Mawaihakona S at Hutt confluence	28/01/2015	85.3	3.98	26.3	19
Waikanae R at Greenaway Rd (RS10)	25/08/2014	123.0	6.61	48.1	27
Mangatarere S at SH 2 (RS50)	05/09/2014	116.8	7.04	44.0	25
Mangatarere S at SH 2 (RS50)	04/02/2015	112.2	5.69	39.1	23

¹Additional macroinvertebrate data are available for these sites but was collected outside of the July 2014 to June 2015 reporting period covered here.
